# High-redshift X-ray sources and their effect on the 21-cm signal

### Anastasia Fialkov, ITC Fellow, Harvard

## **Unobserved Part of The Universe**

#### An outline of cosmic history

- CMB
- Dark Ages
- Cosmic Dawn
- Reionization
- Post EoR

## Answer in Radio: Faint Signal of Neutral Hydrogen

- The "highly forbidden" spin-flip transition  $(2.9 \times 10^{-15} s^{-1})$  happens often enough in the volume of the Universe.
- The Universe is transparent to these photons, they can be observed today

$$\begin{array}{ll} \lambda &= 21 \text{ cm} \\ \nu &= 1420 \text{ MHz} \end{array}$$

$$\begin{array}{ll} n = 1 & n_1 \\ n_0 \\ \textbf{Spin Temperature} \\ n_1/n_0 \equiv 3 \text{ exp}(-T_*/T_{\text{S}}), \\ T_* = 0.068 \text{ K} \end{array}$$

## 21-cm Signal: Tomographic Scan of the Universe

#### An outline of cosmic history

#### Probe of

- Dark Ages
- First Stars and Galaxies
- Reionization

## **International Effort in Radio**

## Role of X-ray Sources in Cosmic History

Heat and partially ionize the IGM far from the source affecting the 21-cm signal

Neutral hydrogen

Ionized

bubble

## What Heated Up the IGM?

#### **Open Questions:**

- Nature of heating sources
- Spectral energy distribution (SED)
- Efficiency
- Time dependence
- X-ray absorption
- Effects of metallicity

#### **Possible Sources:**

- X-ray binaries
- Mini-quasars
- Thermal emission from galaxies
- Shocks
- Dark matter annihilation
- Etc.

## **Spectral Energy Distribution of X-rays**

Hot ISM

Based on Chandra observations (Fragos et al. 2013)

Fragos et al. (2013)

## Were High-z X-ray Sources Soft or Hard?

Details of SED are crucial for the 21-cm signal!

If hard X-rays, effect on the Universe

- Mean free pass is longer
- Delayed heating
- Heating fluctuations are washed out at scales below mfp

# Strong Effect on the IGM and the 21-cm Signal

## 21-cm PS, Hard vs Soft X-rays:

Soft SED: three peaks in PS vs z Hard SED: heating peak is lost

#### Soft X-rays

Hard X-rays Almost uniform heating

Fialkov & Barkana (2014)

## Chandra Observations are Used to Limit f<sub>x</sub>

$$\frac{L_{\rm X}}{\rm SFR} = 3 \times 10^{40} f_{\rm X} \ {\rm erg \ s^{-1}} M_{\odot}^{-1} \ {\rm yr}$$

Unresolved X-ray background yields upper limit on heating ( $f_X$ =10-100).

Also: 21-cm power gives lower limit on cosmic heating ( $f_x=0.001$ ).

(Ali et al. 2015, Pober et al. 2015)

## From 21-cm Signal and X-rays Limits on Cosmic Heating

For atomic cooling, hard SED and  $z_{re} = 6.2$ f<sub>X</sub> <0.01 and f<sub>X</sub> >11 are ruled out!

## Still a wide space to constrain

Cross-correlation with large-scale X-ray background can improve understanding of large-scale effect of X-rays

#### More on cross-correlation is coming out soon!

Group in Munich: B. Ciardi, N. Cappelluti, et al.

- Hydro simulations & post-process with UV+X-rays (Khandai+ 2015)
- Box size ~ 100 Mpc/h
- Star and BH formation is followed from z = 20 to z = 6
- Preliminary results by the end of the year

Kakiichi et al., 2016

Figure 12. Maps of temperature for models GAL (left) and QSO\_UVXsec (right). In both models the sources are turned on in a fully neutral medium at z = 10 and shine for  $10^7$  yr. The maps have a side length of  $50h^{-1}$ cMpc and the width of the slice is  $195h^{-1}$ ckpc. The H II (He III) I-front is shown as blue solid (dotted) contour.

### **Conclusions:**

High redshift X-ray study is curtail for understanding the 21-cm signal & the role and nature of the first heating sources

- 1. Wide surveys: cross-correlation of backgrounds
- Ultradeep observations: properties of point X-ray sources have strong impact on the large scale 21-cm signal
